

Abstract

Reference dictionaries and data dictionaries are used in order to analyze data in data formats, which cannot be directly processed and which are communicated between geodesic units. These dictionaries are transmitted preferably in conjunction with the transmission of the data and they index analyzable data fields in data formats. When a geodesic unit receives a data format that cannot be directly processed, data fields, which can be analyzed by the reference dictionary, can be found and data fields, which cannot be analyzed by a data dictionary, can be utilized.
